## Estimating Gypsy Moth Egg Mass Densities

A fast and accurate method of estimating gypsy moth egg mass densities is needed to monitor gypsy moth populations and to evaluate potential treatment areas. This paper describes a method of estimating gypsy moth egg mass densities based on a USDA Forest Service fixed - and variable - radius plot method<sup>1</sup> and a five-minute walk egg mass count. The latter was developed by the College of Environmental Science and Forestry for the New York State Department of Environmental Conservation (DEC) to select areas for inclusion in New York State's gypsy moth integrated pest management (IPM) program.

Currently, states with large gypsy moth programs utilize a variety of methods and plot sizes to estimate egg mass densities: 1/40th acre, 1/100th hectare, basal area factor (BAF)-10 and BAF-20 prism plots. When egg mass densities are high, sampling is not necessary for trained personnel to determine whether or not an area requires treatment. However, in moderate to low populations surveys are required to obtain reasonably accurate estimates of egg mass density. Field crews must survey many areas and they cannot afford to spend a lot of time at each site. In order to facilitate accuracy and to minimize the time needed to estimate egg mass densities, we compared the 5-minute walk egg mass count method to the variable- and fixed-radius plot method (using the BAF-20 prism).

Five BAF-20 prism plots were established in each of 34 blocks in Orange Co., NY. Plot centers were approximately 2 chains apart (132 ft.) and all trees within each plot were flagged and marked with metal tags. Three egg mass surveys were conducted in these plots (spring 1980, fall 1980, and fall 1981), and the data were converted to estimates of egg masses per acre (em/A). The 5-minute walk method was done as follows: two people started at prism plot 1 and walked for 5 minutes along the line of sample plots and counted new egg masses. The walk ended near prism plot 5, or approximately 8 chains (528 ft.) from the starting point. The average of the two 5-minute walk egg mass counts was plotted against the BAF-20 estimate of egg masses per acre. Regression analysis was used to determine if 5-minute walk egg mass counts and estimates of em/A obtained from the BAF-20 prism plots were correlated. Significant correlations were found for each of the three years of the study. A sample data form for recording egg mass survey data appears at the end of this report.

<sup>1</sup>USDA Agr. Handbk. No. 523, Gypsy Moth Egg-Mass Sampling with Fixed- and Variable- Radius Plots.

This method of estimating egg mass density is useful for agencies that must survey vast acreages to identify areas that should be included in a gypsy moth IPM program. In New York State, areas that meet specified land use criteria must also meet certain egg mass density thresholds before treatment is considered as part of an integrated program. For increasing gypsy moth populations (i.e., egg mass density has increased from previous year), 200 em/A or more must be present before any treatment is considered. In declining populations (i.e., egg mass density has decreased from previous year) 400 em/A is the minimum threshold. These egg mass density thresholds were established by the DEC and are used together with egg viability and parasitism data to identify potential treatment areas. More accurate surveys must be conducted when densities are at or near these em/A thresholds. Under these circumstances, a minimum of three variable- and fixed-radius plots (BAF-20 prism) will provide reliable estimates of egg mass numbers (i.e., when the average of two 5-minute walk egg mass counts is less than 40). The actual number of plots used depends on stand size, stand composition and time available. Densities that are substantially above these minimum thresholds (e.g., 800+ em/A) can be satisfactorily estimated with the 5-minute walk egg mass count (i.e., when the average of the two 5-minute walk egg mass counts is greater than 40).

When the average of two 5-minute walk counts exceeds 40 em, Tables 2 to 4 are used to estimate the egg mass density. The age of the outbreak will determine which table is appropriate; a description of the conditions for each year of an outbreak cycle is given with each table. Table 1<sup>2</sup> is included to help with survey activities in those areas that experience a buildup of the gypsy moth for the first time. Table 5<sup>3</sup> can be used to compute the overstory egg mass density when the BAF-20 prism variable-radius plot method is used. The egg mass density values for all trees surveyed in the BAF-20 prism plots should be summed and then divided by the number of prism points in order to obtain an estimate of overstory em/A. For example, five BAF-20 prism plots are established, tree diameter at breast height (dbh) is recorded to the nearest inch and binoculars are used to count all new egg masses on each tree. The egg mass density value for each dbh is obtained from Table 5 (e.g., 5 egg masses on a 10 inch tree equals an egg mass density value of 183). The egg mass density values for all trees in the five BAF-20 prism plots are summed and then divided by 5 (the number of prism plots used) to obtain an estimate of overstory em/A. Understory egg mass density is determined by counting the

<sup>3</sup>USDA Agr. Handbk. No.523, Gypsy Moth Egg-mass Sampling with Fixed-and Variable-Radius Plots.

egg masses in an 8.3 ft. radius mini-plot (1/200th acre) at each prism point. Egg mass counts are summed over the number of prism points used, multiplied by 200, and divided by the number of prism points. Next, this value is added to the overstory em/A value to obtain the total egg mass density estimate. Understory egg mass surveys using the 8.3 ft. mini-plot should always be taken because gypsy moths in increasing populations tend to lay their egg masses in concealed locations on the ground, under logs and rocks. As the population increases, more egg masses are found on tree boles and the underside of branches. The variable- and fixed- radius plot egg mass survey method is recommended when the population is not extremely high, (less than 800 em/A), therefore, the understory contribution to the total egg mass density will be significant.

This egg mass survey method can be used to augment a permanent sample plot monitoring system. The 5-minute walk egg mass count portion of the method allows for a quick assessment of a particular area and can support the information obtained from permanent sample plots. This approach can easily be incorporated into a state's survey and monitoring program for the gypsy moth.

Summary of Sampling Procedure:

1. Take two 5-minute walks per area counting the new egg masses. Each walk should cover a distance of approximately 525 feet (160 meters). We suggest taking one egg mass count going in one predetermined direction, then turning around and taking the second egg mass count along the same route if one person is surveying. If two people are surveying, then each person should take a 5-minute count going in the same direction.
2. An old-to-new egg mass ratio may have to be determined if the survey crew has a difficult time distinguishing the difference between old and new egg masses. This is especially a problem when surveys are done in the spring instead of the fall of the year. One hundred egg masses should be examined in each area to determine the old-to-new egg mass ratio. If an old-to-new ratio is determined, then during the 5-minute walk all egg masses are counted (old and new). The number of new egg masses counted is determined from the old-to-new ratio. We strongly recommend that egg mass surveys be conducted in the fall of the year when it is easier to distinguish new from old egg masses. We recommend the use of hand-counters when doing the 5-minute walk.

3. If the average of the two 5-minute walk egg mass counts exceeds 40 egg masses,  $\text{em}/\text{A}$  can be estimated using Tables 1-4. The duration of the gypsy moth outbreak in the area will determine which table should be used.
4. If the average of the two 5-minute walk egg mass counts is less than 40  $\text{em}$ , then the variable- and fixed-radius plot method using a BAF-20 prism should be used to estimate  $\text{em}/\text{A}$ . A minimum of 3 prism plots per area should be used. Table 5 can be used to determine the overstory portion of the total estimated  $\text{em}/\text{A}$ . The estimated understory  $\text{em}/\text{A}$  is added to the overstory estimate to obtain a total  $\text{em}/\text{A}$ .

X = Average of Two 5-Minute Walk Egg Mass Counts.

Y = Estimated Egg Masses Per Acre.

$$Y = 20.56 (X) + 14.58$$

$R^2 = 0.66$  (this means 66% of the variation in y is explained by x).

Criteria:

Use this Table (Equation) in areas experiencing an infestation for the first time. The egg mass densities should be very low. Heavy defoliation is not expected in the Spring, but some defoliation is likely.

This Table (Equation) is most accurate for X values between 1 and 21.

X = Average of Two 5-Minute Walk Egg Mass Counts.

Y = Estimated Egg Masses Per Acre

$$Y = 11.26 (X) + 342.16 \quad R^2 = 0.64$$

Criteria:

Use this Table (Equation) in a building gypsy moth population. The first year of heavy defoliation is expected in the Spring. The egg masses are large and healthy. There are more new than old egg masses in the area (very hard to find any old egg masses). This Table (Equation) is most accurate for X values between 40 and 195.

X = Average of Two 5-Minute Walk Egg Mass Counts.

Y = Estimated Egg Masses Per Acre

$$Y = 23.84 (X) + 1434.61$$

$$R^2 = 0.59$$

#### Criteria:

Use this Table (Equation) during the second year of an outbreak. The area should have already experienced one year of heavy defoliation, and a second year of defoliation is expected. The egg mass densities are very high. There are more new than old egg masses, but the new egg masses are smaller than the previous year's egg masses. This Table (Equation) is most accurate for X values between 60 and 340.

X = Average of Two 5-Minute Walk Egg Mass Counts.

Y = Estimated Egg Masses Per Acre.

$$Y = 16.40 (X) + 259.44$$

$$R^2 = 0.81$$

#### Criteria:

Use this Table (Equation) during the third year of an outbreak. The area should have experienced two consecutive years of heavy defoliation. There are more old than new egg masses in the area, and the new egg masses are generally very small (the size of a U.S. dime or smaller). This Table (Equation) is most accurate for X values between 40 and 230.

Table 5. Overstory Egg Masses per Acre Estimate Based on a Basal Area Factor Twenty Prism.

## APPENDIX

This appendix contains two examples using the egg mass survey techniques. In addition, a blank survey form is included.

Example No. 1 had an average of two 5-minute walk EMC's of less than 40. The variable- and fixed radius plot method, using five BAF-20 prism points, resulted in an estimate of 376 EM/A. It was noticed that a change in the forest stand composition occurred after Plot 4 with more oaks occurring in Plots 5-10. Plots 1 to 4 did not experience heavy defoliation (0 to 25%), but trees in Plot 5 suffered heavy defoliation (40 to 100%).

Example No. 2 shows the results of two 5-minute walk EMC's with an average greater than 40. Plots 6 to 10 are a continuation of the line of plots presented in example No. 1, and illustrates the point that by doing a number of 5-minute walk EMC's in an area survey crews can determine the extent of a gypsy moth outbreak. Plots 6 to 10 had an estimated 1018 EM/A using Table 2 and the 5-minute walk EMC method. In comparison, the variable- and fixed-radius plot method yielded an estimate of 843 EM/A. This area suffered heavy defoliation (50 to 100%).

These two examples were chosen to illustrate the point that the 5-minute walk EMC or a number of 5-minute walk EMC's in an area can help determine the borders of a gypsy moth infestation and assist the field crew in establishing potential treatment areas.

## EXAMPLE NO. 1

## GYPSY MOTH EGG MASS SURVEY

COUNTY Orange Co., N.Y.

PESTICIDE \_\_\_\_\_

BLOCK LOCATION W.Mombasha Rd.

DATE SPRAYED \_\_\_\_\_

 AVERAGE OF TWO 5-MINUTE WALK EMC'S

If the average of the two 5-minute walk EMC'S is  $\geq 40$ , then  
 use tables 1-4 to estimate egg masses per acre (EM/A).

Table Used = 

--

EM/A = 

--

If the average is  $< 40$ , then complete Step 2 on the reverse side.

NOTE: If block is sprayed, then cols. 2, 3, 10 and 11 on the reverse side should be completed.

Comments: egg masses are very large; little to no defoliation in 1979; no old egg masses visible. Most of the egg masses in the 5-minute walk were counted during the last minute of the walk. Note that the line of plots is on the border of the outbreak area. Plots 1-4 are in a mixed hardwoods area, which changes to an all oak stand in Plots 5-10. The defoliation results and numbers of egg masses illustrate this change.

		SUM		1679	1	SUM					Avg Defol=27%

EM/A estimates in cols. 5 and 8 are determined from Table 5 by using data in cols. 3-4 and 3-7, respectively.

Prespray overstory EM/A = SUM Col. 5 ÷ No. of prism points.

$$\boxed{336} = \boxed{1679} \div \boxed{5}$$

Prespray understory EM/A = (SUM Col. 6 ÷ No. of prism points) × 200

$$\boxed{40} = (\boxed{1} \div \boxed{5}) \times 200$$

NOTE: One 8.3 ft. radius miniplot EMC required for each prism point.  
 Total prespray EM/A estimate = overstory EM/A + understory EM/A

$$\boxed{376} = \boxed{336} + \boxed{40}$$

:f I = Defoliation estimate at time of spraying.

% Def II = Defoliation estimate at end of larval feeding.

## EXAMPLE NO. 2

## GYPSY MOTH EGG MASS SURVEY

COUNTY Orange Co., N.Y.

 AVERAGE OF TWO 5-MINUTE WALK EMC'S

If the average of the two 5-minute walk EMC'S is  $\geq 40$ , then  
 use tables 1-4 to estimate egg masses per acre (EM/A).

Table Used = 

2
---

EM/A = 

1018
------

If the average is  $< 40$ , then complete Step 2 on the reverse  
 side.

NOTE: If block is sprayed, then cols. 2, 3, 10 and 11 on  
 the reverse side should be completed.

Comments: Little or no defoliation in 1979; egg masses are very large (greater than size of a U.S. quarter); cannot find any old egg masses; little or no egg parasitism (cannot see any exit holes in egg masses). The estimated EM/A using the variable- and fixed-radius plot method with 5 BAF-20 prism points was 843 EM/A.
